# A brief primer on CFL recognition

Given a CFG  $\mathcal{G} := \langle V, \Sigma, P, S \rangle$  in Chomsky Normal Form, we can construct a recognizer  $R_{\mathcal{G}} : \Sigma^n \rightarrow \mathbb{B}$  for strings  $\sigma : \Sigma^n$  as follows. Let  $2^V$  be our domain, 0 be  $\emptyset$ ,  $\oplus$  be  $\cup$ , and  $\otimes$  be defined as follows:

$$s_1 \otimes s_2 := \{C \mid \langle A, B \rangle \in s_1 \times s_2, (C \rightarrow AB) \in P\}$$

e.g.,  $\{A \rightarrow BC, C \rightarrow AD, D \rightarrow BA\} \subseteq P \vdash \{A, B, C\} \otimes \{B, C, D\} = \{A, C\}$

If we define  $\sigma_r^{\rightarrow} := \{w \mid (w \rightarrow \sigma_r) \in P\}$ , then initialize

$M_{r+1=c}^0(\mathcal{G}', e) := \sigma_r^{\rightarrow}$  and solve for the fixpoint  $M^* = M + M^2$ ,

$$M^0 := \begin{pmatrix} \emptyset & \sigma_1^{\rightarrow} & \emptyset & \dots & \emptyset \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \emptyset & \dots & \dots & \dots & \emptyset \\ \emptyset & \dots & \dots & \dots & \emptyset \end{pmatrix} \Rightarrow \dots \Rightarrow M^* = \begin{pmatrix} \emptyset & \sigma_1^{\rightarrow} & \Lambda & \dots & \Lambda_{\sigma}^* \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \emptyset & \dots & \dots & \dots & \emptyset \\ \emptyset & \dots & \dots & \dots & \emptyset \end{pmatrix}$$

$S \Rightarrow^* \sigma \iff \sigma \in \mathcal{L}(\mathcal{G})$  iff  $S \in \Lambda_{\sigma}^*$ , i.e.,  $\mathbb{1}_{\Lambda_{\sigma}^*}(S) \iff \mathbb{1}_{\mathcal{L}(\mathcal{G})}(\sigma)$ .

# Satisfiability + holes (our contribution)

- Can be lowered onto a Boolean tensor  $\mathbb{B}^{n \times n \times |V|}$  (Valiant, 1975)
- Binarized CYK parser can be efficiently compiled to a SAT solver
- Enables sketch-based synthesis in either  $\sigma$  or  $\mathcal{G}$ : just use variables!
- We simply encode the characteristic function, i.e.  $\mathbb{1}_{\subseteq V} : 2^V \rightarrow \mathbb{B}^{|V|}$
- $\oplus, \otimes$  are defined as  $\boxplus, \boxtimes$ , so that the following diagram commutes:

$$\begin{array}{ccc} 2^V \times 2^V & \xrightarrow{\oplus/\otimes} & 2^V \\ \uparrow \mathbb{1}^{-2} \downarrow \mathbb{1}^2 & & \uparrow \mathbb{1}^{-1} \downarrow \mathbb{1} \\ \mathbb{B}^{|V|} \times \mathbb{B}^{|V|} & \xrightarrow{\boxplus/\boxtimes} & \mathbb{B}^{|V|} \end{array}$$

- These operators can be lifted into matrices/tensors in the usual way
- In most cases, only a few nonterminals are active at any given time

# Satisfiability + holes (our contribution)

Let us consider an example with two holes,  $\sigma = 1 \_ \_$ , and the grammar being  $G := \{S \rightarrow NON, O \rightarrow + \mid \times, N \rightarrow 0 \mid 1\}$ . This can be rewritten into CNF as  $G' := \{S \rightarrow NL, N \rightarrow 0 \mid 1, O \rightarrow \times \mid +, L \rightarrow ON\}$ . Using the algebra where  $\oplus = \cup$ ,  $X \otimes Z = \{w \mid \langle x, z \rangle \in X \times Z, (w \rightarrow xz) \in P\}$ , the fixpoint  $M' = M + M^2$  can be computed as follows:

|            | $2^V$   | $\mathbb{B}^{ V }$   | $\mathbb{B}^{ V } \rightarrow \mathbb{B}^{ V }$   |
|------------|---|--|---|
| $M_0$      | $\begin{pmatrix} \{N\} \\ \{N, O\} \\ \{N, O\} \end{pmatrix}$                             | $\begin{pmatrix} \square \blacksquare \square \square \\ \square \blacksquare \blacksquare \square \\ \square \blacksquare \blacksquare \square \end{pmatrix}$   | $\begin{pmatrix} V_{0,1} \\ V_{1,2} \\ V_{2,3} \end{pmatrix}$                               |
| $M_1$      | $\begin{pmatrix} \{N\} & \emptyset \\ \{N, O\} & \{L\} \\ \{N, O\} \end{pmatrix}$         | $\begin{pmatrix} \square \blacksquare \square \square & \square \square \square \square \\ \square \blacksquare \blacksquare \square & \blacksquare \square \square \square \\ \square \blacksquare \blacksquare \square \end{pmatrix}$  | $\begin{pmatrix} V_{0,1} & V_{0,2} \\ V_{1,2} & V_{1,3} \\ V_{2,3} \end{pmatrix}$           |
| $M_\infty$ | $\begin{pmatrix} \{N\} & \emptyset & \{S\} \\ \{N, O\} & \{L\} \\ \{N, O\} \end{pmatrix}$ | $\begin{pmatrix} \square \blacksquare \square \square & \square \square \square \square & \square \square \square \blacksquare \\ \square \blacksquare \blacksquare \square & \blacksquare \square \square \square \\ \square \blacksquare \blacksquare \square \end{pmatrix}$ | $\begin{pmatrix} V_{0,1} & V_{0,2} & V_{0,3} \\ V_{1,2} & V_{1,3} \\ V_{2,3} \end{pmatrix}$ |

# Semiring algebras: Part I

The prior solution tell us whether  $A(\sigma)$  is nonempty, but forgets the solution(s). To solve for  $A(\sigma)$ , a naïve approach accumulates a mapping of nonterminals to sets of strings. Letting  $D = V \rightarrow \mathcal{P}(\Sigma^*)$ , we define  $\oplus, \otimes : D \times D \rightarrow D$ . Initially, we construct  $M_0[r + 1 = c] = p(\sigma_r)$  using:

$$p(s : \Sigma) \mapsto \{w \mid (w \rightarrow s) \in P\} \text{ and } p(\_) \mapsto \bigcup_{s \in \Sigma} p(s)$$

$p(\cdot)$  constructs the superdiagonal, then we solve for  $\Lambda_\sigma^*$  using the algebra:

$$X \oplus Z \mapsto \{w \xRightarrow{+} (X \circ w) \cup (Z \circ w) \mid w \in \pi_1(X \cup Z)\}$$

$$X \otimes Z \mapsto \bigoplus_{w,x,z} \{w \xRightarrow{+} (X \circ x)(Z \circ z) \mid (w \rightarrow xz) \in P, x \in X, z \in Z\}$$

After  $M_\infty$  is attained, the solutions can be read off via  $\Lambda_\sigma^* \circ S$ . The issue here is exponential growth when eagerly computing the transitive closure.

## Semiring algebras: Part II

The prior encoding can be improved using an ADT  $\mathbb{T}_3 = (V \cup \Sigma) \rightarrow \mathbb{T}_2$  where  $\mathbb{T}_2 = (V \cup \Sigma) \times (\mathbb{N} \rightarrow \mathbb{T}_2 \times \mathbb{T}_2)$ . We construct  $\hat{\sigma}_r = \dot{p}(\sigma_r)$  using:

$$\dot{p}(s : \Sigma) \mapsto \left\{ \mathbb{T}_2(w, [\langle \mathbb{T}_2(s), \mathbb{T}_2(\varepsilon) \rangle]) \mid (w \rightarrow s) \in P \right\} \text{ and } \dot{p}(\_) \mapsto \bigoplus_{s \in \Sigma} p(s)$$

We then compute the fixpoint  $M_\infty$  by redefining  $\oplus, \otimes : \mathbb{T}_3 \times \mathbb{T}_3 \rightarrow \mathbb{T}_3$  as:

$$X \oplus Z \mapsto \bigcup_{k \in \pi_1(X \cup Z)} \left\{ k \Rightarrow \mathbb{T}_2(k, x \cup z) \mid x \in \pi_2(X \circ k), z \in \pi_2(Z \circ k) \right\}$$

$$X \otimes Z \mapsto \bigoplus_{(w \rightarrow xz) \in P} \left\{ \mathbb{T}_2(w, [\langle X \circ x, Z \circ z \rangle]) \mid x \in \pi_1(X), z \in \pi_1(Z) \right\}$$

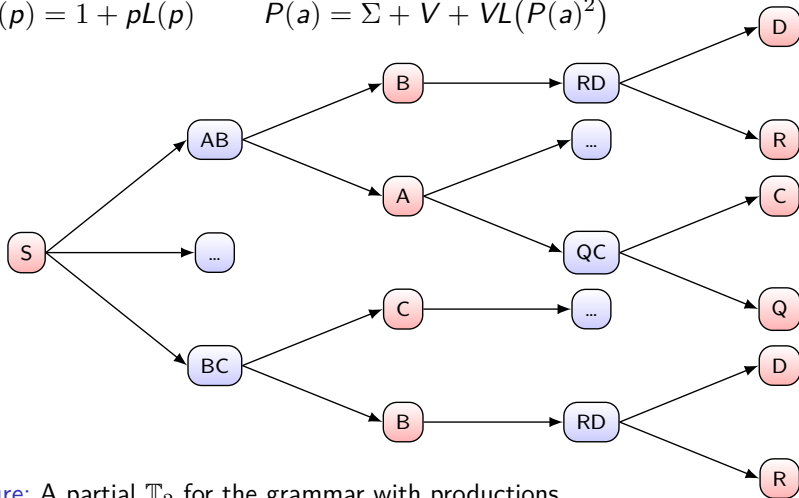

# $\mathbb{T}_3$ join and merge semantics

# Semiring algebras: Part III

$$L(p) = 1 + pL(p)$$

$$P(a) = \Sigma + V + VL(P(a)^2)$$

**Figure:** A partial  $\mathbb{T}_2$  for the grammar with productions  
 $P = \{S \rightarrow BC \mid \dots \mid AB, B \rightarrow RD \mid \dots, A \rightarrow QC \mid \dots\}$ .

# Sampling trees with replacement

Given a probabilistic CFG whose productions indexed by each nonterminal are decorated with a probability vector  $\mathbf{p}$  (this may be uniform in the non-probabilistic case), we define a tree sampler  $\Gamma : (\mathbb{T}_2 \mid \mathbb{T}_2^2) \rightsquigarrow \mathbb{T}$  which recursively samples children according to a Multinoulli distribution:

$$\Gamma(T) \mapsto \begin{cases} \Gamma(\text{Multi}(\text{children}(T), \mathbf{p})) & \text{if } T : \mathbb{T}_2 \\ \langle \Gamma(\pi_1(T)), \Gamma(\pi_2(T)) \rangle & \text{if } T : \mathbb{T}_2 \times \mathbb{T}_2 \end{cases}$$

This is closely related to the generating function for the ordinary Boltzmann sampler from analytic combinatorics,

$$\Gamma C(x) \mapsto \begin{cases} \text{Bern}\left(\frac{A(x)}{A(x)+B(x)}\right) \rightarrow \Gamma A(x) \mid \Gamma B(x) & \text{if } C = \mathcal{A} + \mathcal{B} \\ \langle \Gamma A(x), \Gamma B(x) \rangle & \text{if } C = \mathcal{A} \times \mathcal{B} \end{cases}$$

however unlike Duchon et al. (2004), rejection is unnecessary to ensure exact-size sampling, as all trees in  $\mathbb{T}_2$  will necessarily be the same size.

# A pairing function for replacement-free tree sampling

The total number of trees induced by a given sketch template is given by:

$$|T : \mathbb{T}_2| \mapsto \begin{cases} 1 & \text{if } T \text{ is a leaf,} \\ \sum_{\langle T_1, T_2 \rangle \in \text{children}(T)} |T_1| \cdot |T_2| & \text{otherwise.} \end{cases}$$

To sample from  $\mathbb{T}_2$  without replacement, we define a pairing function:

$$\varphi^{-1}(T : \mathbb{T}_2, i : \mathbb{Z}_{|T|}) \mapsto \begin{cases} \langle \text{BTree}(\text{root}(T)), i \rangle & \text{if } T \text{ is a leaf,} \\ \begin{aligned} &\text{Let } b = |\text{children}(T)|, \\ &q_1, r = \langle \lfloor \frac{i}{b} \rfloor, i \pmod{b} \rangle, \\ &lb, rb = \text{children}[r], \\ &T_1, q_2 = \varphi^{-1}(lb, q_1), \\ &T_2, q_3 = \varphi^{-1}(rb, q_2) \text{ in} \\ &\langle \text{BTree}(\text{root}(T), T_1, T_2), q_3 \rangle \end{aligned} & \text{otherwise.} \end{cases}$$

# Chomsky Denormalization

Chomsky normalization is needed for matrix-based parsing, however produces lopsided parse trees. We can denormalize them using a simple recursive procedure to restore the natural shape of the original CFG:

---

**Algorithm** Rewrite procedure for tree denormalization

---

```
procedure CUT(t: Tree)
  stems  $\leftarrow$  { CUT(c) | c  $\in$  t.children }
  if t.root  $\in$  ( $V_{G'}$  \  $V_G$ ) then
    return stems
  else
    return { Tree(t.root, stems) }
  end if
end procedure
```

---

All synthetic nonterminals are excised during Chomsky denormalization. Rewriting improves legibility but does not alter the underlying semantics.

# Error Correction: Sketch Templates

To sample  $\sigma \sim \Delta_q(\underline{\sigma})$ , we could enumerate a series of sketch templates  $H(\sigma, i) = \sigma_{1\dots i-1} \_ \sigma_{i+1\dots n}$  for each  $i \in \cdot \in \{^n_d\}$  and  $d \in 1 \dots q$ , then solve for  $\mathcal{M}^*_\sigma$ . If  $S \in \Lambda^*_\sigma$  has a solution, each edit in each  $\sigma' \in \sigma$  will match exactly one of the following seven edit patterns:

$$\text{Deletion} = \left\{ \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \gamma_{1,2} = \varepsilon \right.$$

$$\text{Substitution} = \left\{ \begin{array}{l} \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \gamma_1 \neq \varepsilon \wedge \gamma_2 = \varepsilon \\ \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \gamma_1 = \varepsilon \wedge \gamma_2 \neq \varepsilon \\ \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \{\gamma_1, \gamma_2\} \cap \{\varepsilon, \sigma_i\} = \emptyset \end{array} \right.$$

$$\text{Insertion} = \left\{ \begin{array}{l} \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \gamma_1 = \sigma_i \wedge \gamma_2 \notin \{\varepsilon, \sigma_i\} \\ \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \gamma_1 \notin \{\varepsilon, \sigma_i\} \wedge \gamma_2 = \sigma_i \\ \dots \sigma_{i-1} \begin{array}{|c|c|} \hline \gamma_1 & \gamma_2 \\ \hline \end{array} \sigma_{i+1} \dots \quad \gamma_{1,2} = \sigma_i \end{array} \right.$$

But this is very expensive, requiring  $\tilde{O} \left( \binom{n}{d} |\Sigma + 1|^{2d} \right)$  to search  $\{^n_d\} \times \Sigma_\varepsilon^{2d}$ .

# Error Correction: d-Subset Sampling

Next, suppose  $U : \mathbb{Z}_2^{m \times m}$  is a matrix whose structure is shown in Eq. 1, wherein  $C$  is a primitive polynomial over  $\mathbb{Z}_2^m$  with coefficients  $C_1 \dots C_m$  and semiring operators  $\oplus := \vee, \otimes := \wedge$ :

$$U^t V = \begin{pmatrix} C_1 & \dots & C_m \\ \top & \circ & \dots & \circ \\ \circ & & \ddots & \\ \circ & \dots & \circ & \top & \circ \end{pmatrix}^t \begin{pmatrix} V_1 \\ \vdots \\ V_m \end{pmatrix} \quad (1)$$

Since  $C$  is primitive, the sequence  $\mathbf{S} = (U^{0 \dots 2^m-1} V)$  must have *full periodicity*, i.e., for all  $i, j \in [0, 2^m)$ ,  $\mathbf{S}_i = \mathbf{S}_j \Rightarrow i = j$ . To uniformly sample  $\sigma$  without replacement, we first form an injection  $\mathbb{Z}_2^m \rightarrow \left\{ \binom{n}{d} \right\} \times \Sigma_\epsilon^{2d}$  using a combinatorial number system, cycle over  $\mathbf{S}$ , then discard samples which have no witness in  $\left\{ \binom{n}{d} \right\} \times \Sigma_\epsilon^{2d}$ . This method requires  $\tilde{O}(1)$  per sample and  $\tilde{O}\left(\binom{n}{d} |\Sigma + 1|^{2d}\right)$  to exhaustively search  $\left\{ \binom{n}{d} \right\} \times \Sigma_\epsilon^{2d}$ .

# Levenshtein reachability and monotone infinite automata

## MAIA

## CFG

$$S \Rightarrow \{\cdot \in Q \mid \delta(\cdot, q_{n,0}) \leq k\}$$

$$* \Rightarrow \{\cdot \in \Sigma\}$$

$$\{q_{i,j} \Rightarrow \{q_{i,j-1}*\} \mid i,j \in [1,n] \times [1,k]\}$$

$$\{q_{i,j} \Rightarrow \{q_{i-1,j-1}*\} \mid i,j \in [1,n] \times [1,k]\}$$

$$\{q_{i,j} \Rightarrow \{q_{i-1,j}\sigma_i\} \mid i,j \in [1,n] \times [0,k]\}$$

$$\{q_{i,j} \Rightarrow \{q_{i-2,j-1}\sigma_i\} \mid i,j \in [2,n] \times [1,k]\}$$

**Figure:** Bounded Levenshtein reachability from  $\sigma : \Sigma^n$  is expressible as either a monotone acyclic infinite automata (MAIA) populated by accept states within radius  $k$  of  $S = q_{n,0}$  (left), or equivalently, a left-linear CFG whose productions bisimulate the transition dynamics up to a fixed horizon (right), accepting only strings within Levenshtein radius  $k$  of  $\sigma$ .

# The Chomsky-Levenshtein-Bar-Hillel Construction

The original Bar-Hillel construction provides a way to construct a grammar for the intersection of a regular and context-free language.

$$\frac{q \in I \quad r \in F}{(S \rightarrow qSr) \in P_{\cap}} \quad \frac{(q \xrightarrow{a} r) \in \delta}{(qar \rightarrow a) \in P_{\cap}} \quad \frac{(w \rightarrow xz) \in P \quad p, q, r \in Q}{(pwr \rightarrow (pxq)(qzr)) \in P_{\cap}}$$

The Levenshtein automata is another kind of lattice, not in the order-theoretic sense, but in the automata-theoretic sense.

$$\begin{array}{c} \frac{s \in \Sigma \quad i \in [0, n] \quad j \in [1, k]}{(q_{i,j-1} \xrightarrow{s} q_{i,j}) \in \delta} \uparrow \quad \frac{s \in \Sigma \quad i \in [1, n] \quad j \in [1, k]}{(q_{i-1,j-1} \xrightarrow{s} q_{i,j}) \in \delta} \nearrow \\[10pt] \frac{s = \sigma_i \quad i \in [1, n] \quad j \in [0, k]}{(q_{i-1,j} \xrightarrow{s} q_{i,j}) \in \delta} \rightarrow \quad \frac{s = \sigma_i \quad i \in [2, n] \quad j \in [1, k]}{(q_{i-2,j-1} \xrightarrow{s} q_{i,j}) \in \delta} \nearrow \\[10pt] \frac{}{q_{0,0} \in I} \text{INIT} \quad \frac{q_{i,j} \quad |n - i + j| \leq k}{q_{i,j} \in F} \text{DONE} \end{array}$$

# Abbreviated history of algebraic parsing

- Chomsky & Schützenberger (1959) - The algebraic theory of CFLs
- Cocke–Younger–Kasami (1961) - Bottom-up matrix-based parsing
- Brzozowski (1964) - Derivatives of regular expressions
- Earley (1968) - top-down dynamic programming (no CNF needed)
- Valiant (1975) - first realizes the Boolean matrix correspondence
  - Naïvely, has complexity  $\mathcal{O}(n^4)$ , can be reduced to  $\mathcal{O}(n^\omega)$ ,  $\omega < 2.763$
- Lee (1997) - Fast CFG Parsing  $\iff$  Fast BMM, formalizes reduction
- Might et al. (2011) - Parsing with derivatives (Brzozowski  $\Rightarrow$  CFL)
- Bakinova, Okhotin et al. (2010) - Formal languages over GF(2)
- Bernady & Jansson (2015) - Certifies Valiant (1975) in Agda
- Cohen & Gildea (2016) - Generalizes Valiant (1975) to parse and recognize mildly context sensitive languages, e.g. LCFRS, TAG, CCG
- Considine, Guo & Si (2022) - SAT + Valiant (1975) + holes
- **Considine (2023) -  $\mathbb{T}_3$  completion + distinct tree sampling**

# Uniform sampling benchmark on natural syntax errors

**Figure:** Repairs discovered before the latency cutoff are reranked based on their tokenwise perplexity and compared for an exact lexical match with the human repair at or below rank  $k$ . We note that the uniform sampling procedure is not intended to be used in practice, but provides a baseline for the empirical density of the admissible set, and an upper bound on the latency required to attain a given precision.

# Adaptive sampling benchmark on natural syntax errors

**Figure:** Adaptive sampling repairs. The red line indicates Seq2Parse precision@1 on the same dataset. Since it only supports generating one repair, we do not report precision@k or the intermediate latency cutoffs.
